When in HCL, big boli were given by the user, and the loop had no business to give big ones or top. But this is fundamentally different now.  So, first we must enable our loop to overcome the narrow safety restrictions for SMB size that were appropriate in HCL.  2.1 SMB Range Extention (preferences/OpenAPS SMB/autoISF settings/smb delivery settings/smb_max_range_extension)  Full Looping requires bigger SMB sizes. Setting 120 minutes of basal as max. SMB size as enabled in AAPS Master will rarely suffice.  In AAPS Preferences/OpenAPS SMB/autoISF settings/smb delivery settings, set SMB/UAM max_range_extension) to 2.0. That doubles the allowed max. size, for start.  Even better, you could determine an estimate for your initial setting using the profile hele

	nor
in <u>section 4.6</u> (if already launched Prior, you can proceed as in the following descript	•
19 I will use the symbol,, to denote where you would use your numbers. My numbers	
I use for the same situation will be in parentheses (U).	ırıaı
In full loop, you want to get at least half of our required meal bolus in 10 minutes, through	rh 2
22 SMBs. To do that, you need U (2 U) per SMB on average, and because the bolus s	
tend not to be equal when requested by the Loop, you should have at least U (3 U)	
the allowable SMB size. Your hourly basal is around U (0.6 U), i.e. AAPS Master will	
allow a max. 2 times that hourly basal which = $\dots$ U (1.2 U) per SMB, because of the m	
min of basal setting's max 120 min. size limitation.)	ιαλ
27	
To avoid the requested SMBs reduced in size by safety settings, you need to make further settings.	ina
29 adjustments in AAPS/ Preferences:	iig
30	
31 2.2 Max and Min autoISF Ratio 32 (preferences/OpenAPS SMB/autoISF settings/autoISF_min and autoISF_max)	
33	
34 Set <b>autoISF_max</b> = 2.0 (This allows up to doubling of ISF aggressiveness if "requested by the	
weights" (see <u>section 4</u> ). You can sharpen further, later.	,
For situations of reduced insulin sensitivity, you must specify, in your settings (preference)	200)
also what your lower limit (for weakening of ISF, compared to profile ISF) may be.	, <del>c</del> 3)
autolSF_min should be set to 0.5, or even lower.	
39	

40 41	2.3 SMB Delivery Ratio (preferences/OpenAPS SMB/autoISF settings/smb delivery settings/smb_delivery_ratio)
42	
43	Increase fixed <b>smb_delivery_ratio</b> from 0.5 to 0.6. This results in the algorithm generally
44	demanding 20% more insulin (in the calculation it does every 5 minutes). This can be sharpened
45	significantly more (going toward 1.0),later.
46	The smb_delivery_ratio can also be set dynamically (changing with glucose level). This
47	seems a feature geared more towards hybrid closed loop applications.
48	
49	If you have an extremely low hourly basal rate, you may have to use a higher range extension
50 51	along with adjusting settings such as <b>bgAccel_ISF_weight</b> , as discussed in section 4.2
52	2.4 Safety Against too Aggressive Settings: iobTH
53	
54	A safety net is needed because autoISF shoots big SMBs at rising glucose levels, and you do not
55	want to bounce into the ultimate iobMAX safety setting too often.
56	
57	Therefore we install an iob threshold (iobTH) which, when, and as long as, exceeded, shuts SMBs
58	off.
59	autoISF 3.0 totally changes how iobTH is accessed and modulated. (Before it had been done via
60	an Automation).
61	iobTH is now a parameter in <b>AAPS preferences</b> , defined there as fraction of your set maxIOB:
62	/OpenAPS_SMB/autoISF_settings/Full_Loop_settings: iob_threshold_percent,
63	
64	First, check whether your maxIOB is set reasonably, near the max level of iob <u>you</u> had ever
65	needed in your past looping history; for instance 10 U.
66	
67	Then look at your meal spectrum, and what bolus size, and iob level (including SMBs) was useful
68	in high carb meals to control your glucose (for instance 8 U).
69	
70	Then assume you want to approach no more than about 75% of that level by rapid SMB "fire", after
71	a meal related bg rise is seen (6 U).
72	
73	That gives you the iob_threshold_percent to enter = desired SMB amount / iobMAX (In the
74	example it would be 0.6).
75	
76	In <u>section 4.6</u> you find <i>(if already launched</i> a profile helper to guide you through your
77	calculation.

78	
79	Note that
80	<ul> <li>the last SMB given can exceed that level by max +30% of the active iobTH.</li> </ul>
81 82	<ul> <li>thereafter (until iob falls below iobTH) only %TBRs supply more insulin, if calculated as still required.</li> </ul>
83 84 85	<ul> <li>in low carb meals, that iobTH level should not be reached =&gt; the autoISF parameters         ("weights") need to be tuned carefully, so SMB sizes are not always huge and bounce         against the iobTH restriction, but show different behaviour for different meals</li> </ul>
86 87 88	<ul> <li>autoISF 3.0 contains a function to auto-adjust iobTH with TT set: Dynamic iobTH, see sections 3.3 and 6.1.</li> </ul>
89 90 91 92 93	Note: Shutting off SMBs due to iobTH does <u>not</u> rely on an odd TT or target running - but the even/odd logicis remains useful in different contexts than iobTH.  With older autoISF variants, the odd TT SMB shut-off above iobTH in an Automation had been a bridging solution
94 95	All above discussed settings must be made in AAPS/preferences.
96 97 98	To enable going into FCL mode, additional settings must be made in /preferences/SMB/autoISF, as discussed in detail in <u>sections 3-4.</u>
99 100 101	Once all this set-up is in place, you can enter/exit FCL (for initial tuning or for everyday utilization) via just tapping on the green/violet closed loop icon (if already launched) of your AAPS main screen (else must do it in AAPS/Preferences/OpenAPS SMB/autoISF).
102 103 104	2.5 EatingSoon TT?
<ul><li>105</li><li>106</li><li>107</li></ul>	Your FCL works best if you start meals at below-target glucose values, and ideally have a bit of positive iob at meal start. Also, a low temp. glucose target helps making SMBs (that "aim at it") a bit bigger
107	bigger.
<ul><li>109</li><li>110</li><li>111</li></ul>	Setting an EatingSoonTT well ahead of meal start <i>can</i> therefore be an excellent idea.  However, if (as to be expected) your loop anyways always regulates you down to near-target, the effect from setting an EatingSoonTT will be limited.
112	

The good news therefore is: Setting an  ${\bf Eating Soon TT}$  is not required for autoISF FCL.

113

115	Note that the goal of having a low glucose target to aim at can also be achieved without setting an
116	EatingSoonTT, by automatically setting a low TT just around the time when your loop gives first
117	SMBs. For this you can define an <b>Automation</b> like: CONDITIONS: likely meal time of day + 1st
118	sign of a beginning meal + iob under (?) U (to kick in only in initial phase) + no TT running
119	ACTION: set TT=~74 for ~30 minutes

Note for users of previous autoISF versions: You do not need the other Automation any longer, that previously was needed to shut off EatingSoonTT before iobTH is reached. autoISF 3.0 ff integrates iobTH and the associated temp. SMB shut-off into the algorithm, rather than requiring yet another user Automation for that.

You might prefer working with a pre-set low profile target (especially in case you often experience elevated glucose levels before the respective meal time slot):

- If you have relatively fixed meal time slots in the 24 hours of the day, you could set the **target glucose** values **in your profile** accordingly. So e.g. 11-15h target 76 if you almost always start a lunch between 11:45 and 14:30h.

If you have rather irregular habits, it is more worthwhile to **manually** set an **EatingSoonTT** (which is quite time-uncritical) well before the start of a meal, or even (latest) when the first SMB is about to be triggered by your loop.

 As eluded to above, if your glucose is not elevated as you approach the meal (this should be the norm), you do not have to bother with setting an EatingSoonTT at all. Just have the afore-mentioned Automation help optimize initial SMB sizes.

FCL works in principle also **without** setting an EatingSoonTT. Try for yourself whether you loose any performance via the totally hands-off way.
